

Abstract

A method and system is generally directed to synchronizing the language used for applications and the language used for information provided across a network. The client language that is associated with the language used for applications on a
5 computing device is detected along with the services language. The services language corresponds to the language used for the user interface of network materials, such as web sites and help pages. The services language is stored online so that the services language and the client language may be made to correspond to one another despite the user moving from online to offline or from one computing device to another, allowing for a
10 consistent user experience.
